1 Summary

Even if leisure time boating - and sailing in particular - is considered a rather environmentally friendly hobby and of importance for one’s relationship with nature, it can also have negative side effects for the fragile Baltic Sea. One part of leisure boating that has a direct negative environmental impact is emptying sewage waste from leisure boats to the sea. This contributes to the increasing overflow of nutrients in the Baltic Sea, causes further eutrophication and poses a risk for harmful substances to enter the sea, which is already severely eutrophicated and polluted.

This project work was carried out at the Water centre for innovation (Utvecklingscentrum för vatten – UCV), a municipal company in Norrtälje, Sweden, as part of the BATSECO-Boat project, a project under the EU Central Baltic Programme. The aim of this work is to give an overview of the types of technical solutions present in the market, and especially to understand what the sources of the most common problems related with the use of pump-out stations are and to offer practical solutions to improve the sewage collecting service.

The technology assessment consists of two parts: The market investigation and the study of the quality of the service.

The market investigation aimed to give an objective overview of what is the market offer in the Sweden, Finland, Estonia and outside the project area. The investigation was carried out by interviewing producers, municipal employees, ports managers.

In the study of the service quality the project team investigated if the market is able to meet users’ needs, maintenance technicians and ports managers’ needs, and what the main causes of malfunctions and of users’ complaints are.

The study of the quality of the service was done by having a first-hand experience of the use of pump-out stations during a series of field trips in the Stockholm and Turku archipelago, and by interviewing the different actors: Interviews to ports managers and maintenance technicians have been done in person or via telephone, while boat users have been interviewed personally during the field visits and via an electronic survey sent to various boat clubs in Sweden and Finland. Boat and pontoon producers have been interviewed as well during the visits to the Stockholm and Helsinki boat fairs.

The project team proposed some technical suggestions to improve the sewage collecting for leisure boats. An important result of the project are the recommendations for the requirements to set when buying a new pump-out station: Public procurement for the purchasing of new pump-out stations is a means to improve the service and to give an input to the market.
2 Introduction

BATSECO-BOAT project, a project under the EU Central Baltic Programme, improves the capacity and service level of sewage collecting in small boat ports in Estonian coast and in Finnish and Swedish archipelagos. The project focuses on finding and investing in best solutions for sewage collecting pump-out stations and implementing digital technology for easily locating and monitoring of the available sewage collecting stations. The cross-country collaboration promoted by the project works towards sustainable boat tourism in the Baltic sea and improving the health of the sea.

The work done by UCV in the project contributes to develop an informed decision-making process for municipalities for management of boat latrine waste by spreading knowledge about appropriate boat latrine waste handling technology and user preferences.

3 Background

3.1 Environmental policies implementation in Sweden, Finland and Estonia

Across the Baltic countries environmental policies have been implemented in order to reduce eutrophication and increase boaters' awareness regarding the dumping of sewage water directly into the sea.

A national law forbids dumping in the sea both in Finland (2005) and in Sweden (2015), while Estonia follows the HELCOM recommendations.

Estonia has a recreational craft register for boats with LOA (Length Overall) 2,5 - 24 m with about 33000 boats registered. There are no statistics regarding the toilet systems, but the Estonian Maritime Administration estimates that the 10% of the boats registered have a toilet on board. The data are updated to 2019. Surveys about the toilet systems of small boats have been conducted in Sweden (2015) and Finland (2017) by the national transport agencies. The surveys assess many aspects related to the small boats, the complete studies are mentioned in the references of this report.
Focusing only on the information related to the toilet systems on board the data can be summarized as following:

**Type of toilet (Sweden) %**

<table>

3.2 **Geographical conditions**

Not all the technical solutions are suitable for the three countries involved in the project. Sweden and Finland have a very similar geographical situation: The coast is protected by the archipelago from wind and waves. Moreover, in many islands there is no connection to the centralized system, in terms of wastewater and electricity: Here the need of having floating solutions that can be easily moved and that do not require electricity if equipped with hand pumps.

On the contrary, this kind of solutions cannot be used in Estonia, where the exposed coastline allows to install only land-based solutions.

3.3 **Different technical solutions for pump-out stations**

3.3.1 **Type of stations**

- Land based pump-out stations: The most widely used technical solution. Their placement must be carefully considered, in order to be easily accessible by boaters.

- Portable stations: This type of pump-out station is handy in the way that it can be carried to the boat without the boat needing to be moved. They have a small capacity and require extra work to move the station.

- Floating stations: They can be used only in locations protected from wind and waves. They can be placed outside the harbour and be moved whenever this is needed. Floating stations with hand pump and a tank can be used in those islands where there is no possibility to have electricity and wastewater connection to the municipal network.

3.3.2 **Type of pumps**

- Membrane or diaphragm pumps: This kind of pumps can displace a great volume of material and they are quite wear resistant, as the friction points are very limited since the only section in a diaphragm pump in contact with the fluid is the diaphragm. They do not provide high pressure, which is important when delivering material over a very long distance. Some users have complained about the membrane getting worn and needs to be replaced after a couple of years. It is not a complicated procedure, the trouble has rather been to track down the correct replacement membrane.

- Impeller pumps need to be equipped with an additional grinder to be able to pump sewage water with larger particles.

- Vacuum pumps: Different types of vacuum pumps are used for blackwater systems in household on-site systems, in airplanes and ferries. Some vacuum systems are never in contact with the liquids, they only evacuate air from the holding tank and produce a suction that moves the liquid. Other
manufacturers build their vacuum pump in combination with a grinding pump that chops up the particles and pumps it to the holding tank.

- Eccentric pumps: Consist of an eccentric “screw-rod” that rotates in a rubber housing. The cavity between the rod and the housing moves as the rod turns, transporting the liquid in the pump from one side to the other. This kind of pumps are common in pumping stations for household sewages, for example, but must be equipped with a shredder when pumping liquids containing solid objects.

- Peristaltic pumps: A wheel resembling a cogwheel squeezes a hose or a soft tube, moving the liquid in the hose or tube forward. The pump type is common in dosing systems and for chemicals that are corrosive to metals, since the liquid does not have to leave the pipe when being pumped. One drawback of the system is that the pipe or hose get worn and have to be replaced regularly.

### 3.3.3 Connection to the wastewater treatment plant

The pump-out stations are often directly connected to the municipal wastewater system, but in some cases they collect the sewage in a septic tank. This is the case of most of the floating pump-out stations, where the sewage is collected in a floating sewage tank. The advantage with the floating holding-tank station is that it can be placed far from the municipal infrastructure and does not have to be close to the shore. Some of the disadvantages are that in some cases these floating solutions are not very stable, as the holding tank varies in density when it fills up, they must be emptied with a tank vessel and they tend to smell as the gases evacuate from the tank. When logistically possible a land-based station directly connected to the municipal sewage system is to be preferred. Land based pump-out stations also have better accessibility, making the service easier and cheaper.
4 **Methods**

The project team studied the market offer in Sweden, Finland and Estonia and investigated the main technology producers outside the project area.

In order to understand how to improve the quality of the service of the sewage collecting systems, the project team has interviewed different actors, such as pump-out stations operators, maintenance technicians, boat users, and has visited and tested some pump-out stations in the Stockholm and Turku archipelago.

The goal of this part of the work is to understand how to make the sewage collecting service as simple as possible both for the users and for the maintainers of the stations by suggesting simple practical solutions.

4.1 **Market investigation**

The project team conducted a market investigation by interviewing technology producers and ports managers to give an overview of the different solutions present in the market of the countries involved in the project and to present the main technology producers or retailers outside the project area.

4.2 **Stations operators’ interviews**

The aim of this series of interviews was to identify the issues related with the operation and maintenance of the stations. The project team has interviewed ports and marina managers and maintenance technicians, since the harbours have usually a maintenance contract with an external enterprise.

Reducing the downtime for an equipment that is used for a very short period during the year is essential, but it is also important that boaters use the stations carefully and in a proper way. The questions asked during these interviews are reported in the Attachment III.

4.3 **Boat users’ survey**

Boat users have been asked about their habits and their experiences with the pump-out stations by interviewing them in person during the field trips and by an electronic survey that has been sent to different boat clubs in Sweden and Finland. Boaters’ survey results are reported in Attachment II.

4.4 **Field trips**

The project team has conducted a series of field trips to assess the spectrum of different issues related with the pump-out stations. The stations that have been visited are in Sweden in Stockholm archipelago and in Finland in Turku archipelago, for considering the geographical conditions these places are suitable for different types of solutions.

**Choice of the stations to visit**

During the visits the project team had a first-hand experience of different kind of solutions and interviewed the ports managers for a better understanding of the operation and maintenance of the pump-out stations.
The stations have been chosen based on:

- type of station (stationary, mobile, floating)
- type of pump (hand pump, membrane pump, vacuum pump, etc.)
- destination of the sludge (direct connection to a municipal wastewater treatment plant, storage of the sludge in a tank)
- owner of the station

Pump-out stations visited in Sweden:

- Arholma
- Gräddö
- Svinninge Marina
- Svinninge boat club
- Vaxholm
- Norrtälje guest harbour
- Norrtälje segelsällskap
- Utö

Fig. 4.4 a – The floating station in Gräddö, in the Norrtälje archipelago

Fig. 4.4 b – The sewage collecting system in Utö, that consists in pumping points and a remote pump located in a pump-house.
Pump-out stations visited in Finland:

- Naantali
- Pargas
- Nauvo
- Kasnäs
- Örö
- Peterzens
- Reso

Fig. 4.4 c - Sewage collecting system in Nauvo. In clockwise order: the peer, the suction point, the portable hose, the pump station.
Fig. 4.4 d - Örö floating pump-out station. In the third picture it is possible to see the mechanism that indicates when the tank is full.
5  Results

5.1  Market overview

Pump-out stations production or selling is usually a non-core business activity.

In Estonia the market is relatively small, due to different socio-economical context, geographical conditions and different environmental policy compared to Sweden and Finland. The market situation in Sweden and Finland is quite similar, with local and international producers present in the market. In these countries technology producers or retailers report about a decreasing demand for new pump-out stations, despite the intense boat tourism, and ask for a more severe implementation of the environmental law.

The investigation has been conducted in an objective manner, the website of every producer can be found in this report and the reader is welcome to contact the producers for more detailed information on the products.

The list of producers might not be complete, and it can also vary over time. The prices, when reported, are only indicative.

The results of the market investigation are presented in the Attachment I of this report.

5.2  Boat users’ survey

At the time of this preliminary report the project team has received the answers only from the survey in Sweden. The inputs from the survey contributed to identify the most recurrent problems regarding the use of the pump-out stations. It is also important to highlight that users tend not to like hand-pumps because they require a certain amount of effort for using it, and they would appreciate the presence of more land toilets, also considered that 89% of leisure boats in Sweden do not have a toilet on board.

Boaters’ survey results are reported in Attachment II.
5.3 **Quality of the service: Major problems related with the operation of the stations**

Combining the information from the user survey, the ports managers and maintenance technicians’ interviews, and the field trips the project team has individuated some major problems related with the operation of the pump-out stations that might discourage users from using this type of facilities and that make the work of maintenance technicians more difficult.

1) **Lack of instructions or instructions not readable**

Not clear instructions can lead to an improper use of the pump-out station with ensuing problems for the functionality of the station. Among the stations that the project team has visited only a couple were not provided with instructions at all or the instructions were ruined and not readable.

The first recommendation is to always locate the instructions at a height that allows everybody to read them.

The Baltic sea has an intense marine tourism with boaters from different countries. In order to overcome language problems, having instructions in both the local language and in English might not be enough, it would be recommendable to have also images that illustrate the operations to execute to empty the boat holding tank.

![Two examples of instructions: The second one is understandable by everyone thanks to the illustrations.](image-url)
2) **Hose not long enough**

When interviewing boat users, some have mentioned that they had trouble in using the pump-out stations because the hose had not a proper length to arrive to the boat’s deck waste fitting.

Many suppliers provide hoses with different length, the recommendation is for the port managers to take into consideration this issue and choose the appropriate length depending on the location of the station. Another option is to have two hoses of different length available at the station.

3) **The hose nozzle of the stations is not suitable for all the boat’s deck waste fitting**

In 2000 the ISO standard 4567 has been repealed by the standard ISO 8099: 2000. One of the reasons why this new standard came about was that people would not need to use an adapter between the boat and the suction nozzle to reduce the emissions when sucking and cleaning the adapter. In 2018 a new version of the standard has been published, the ISO 8099:2018, but it does not report changes to the fitting dimensions, just the following statement: *The cap retention system, if used, shall not impede the proper function of the pump-out*.

Albeit almost 20 years have passed since the adoption of the new standard, it is not uncommon that the hose nozzle of the stations is not suitable for the boat’s deck waste fitting. A solution might be to have different nozzles at the station, but they need to be well anchored, as a producer suggested, so that they cannot be stolen or dropped.

The experience of the field trips is that in Sweden and Finland the conic nozzle is one of the most used and this one fits well with different kind of boat’s deck waste fitting.

![Fig. 5.3 b – Conic hose nozzle](image-url)
4) **Difficulty at creating vacuum conditions when using the pump**

If the hose nozzle of the station does not fit well with the boat's deck waste fitting it is hard to pump because air is entering in the deck fitting. In order to create vacuum, some people use some tissue that can be sucked by the pump and ruin it.

A possible solution for this inconvenient is to have the pump-out nozzle equipped with a sucker, that allows to create the vacuum:

![Image of a floating station with a sucker-equipped hose nozzle](image)

**Fig. 5.3 c – The hose nozzle of this floating station is equipped with a sucker, that makes it easier to have a vacuum condition.**

5) **The plexiglass piece of the hose gets often broken**

Many modern pumps have a plexiglass part that allows users to see if the pump is working. Unfortunately, it can happen that boaters break this plexiglass piece and the station is than out of service until it is repaired.
6) Accessibility to the stations

Accessibility to a pump-out station in terms of location is not an easy issue to solve. BATSECO-Boat project is investigating boat traffic to individuate the best locations for the new pump-out stations in Norrtälje municipality. What boaters complain of is the fact that they have to enter all the way into a harbour in order to empty their holding tank. In this region one of the ways to solve this problem might be using floating stations, but apart from the logistic that needs to be studied, some of these kinds of stations are not always easy to access due to difference in height with the boats. Keep the Archipelago Tidy (KAT), a Finnish partner in the project, has recently bought a floating pump-out station that can solve this problem: The floating pontoon has steps on one side in order to have two different heights and be easily accessible by different types of boats.

Fig. 5.3 d – Floating pump-out station in Finland: The pontoon has steps on one side in order to make it easily accessible to higher boats.

7) Transportstyrelsen app is not always updated

The Swedish national transport agency has created an app (Hamnkarta) that allows to localize all the pump-out stations for leisure boats in Sweden. The app gives the exact coordinates of the stations and there is the option for the users to report malfunctions. On one hand this is very useful for other users to know whether a station is working or not, but on the other hand the responsibility to update the state of the station is only on the users, without any warranty of having an updated information on the state of the facility.

When a fault is reported, the manager of the station (municipality, boat club, regional organizations, marinas, etc.) should be demanded to fix the station timely and then update the status of the station in hamnkartan.
8) **Edge or perimeter of the floating stations or peer too sharp**

It is not rare that the edges of a floating pump-out station or of a peer are too sharp or that the shielding system is not durable, ensuing aesthetic damages or even more serious structural damages to the boat.

A solution adopted by some maintenance operators is to use a hose to create a shielding system, by cutting, bending and hardening it. In their experience this is a durable remedy.

![Fig. 5.3 e – Two floating stations: The station on the left has no shielding system on the edge which can cause aesthetic or more severe damages to the boat.](image)

![Fig. 5.3 f – Shielding system on a peer. As it is possible see from the picture a hose has been added to a previous but not functional system.](image)
9) Users forget to close the hose valve

Some stations that work with the vacuum technology are activated by opening a valve located on the hose. When the user has finished pumping it is important to close the valve, otherwise the pump continues sucking air and this can cause problems to the engine. It is important then to highlight the step of closing the hose valve in the instructions.

10) Evacuation column not efficient

Floating stations are provided with an air evacuation column in order to prevent bad odours, but they are not always efficient. The evacuation system has to be dimensioned in a proper way and tall enough to avoid this inconvenience to boaters.

11) Extra options can lead to extra problems

Some stations are equipped with a mechanism to roll back the hose after the use, which on one hand is an extra comfort but on the other hand is a source of extra work for maintenance operators. The suggestion is to keep the station as simple as possible in order to limit sources of malfunction.

12) Problems related to the logistic of station

The pump-out station has been considered as a whole with the wastewater system. During the field trips the project team has visited a floating station connected to the municipal wastewater treatment plant through a pipe running in the sea. This station has an electric screwing pump with a rubbery gasket that at some point got dried and broke. In order to prevent this from happening again the maintenance operators installed a pump that pumps sea water into the system, so that the gasket does not get dry. This has been a good solution for this kind of system, but if the station was not directly connected to the wastewater treatment plant but rather to a tank this would not have been an efficient solution since it would fill the tank faster. This is an example of the importance of considering the whole system when choosing the technology to purchase.

13) Difficulty in getting spare parts

Some harbours have experienced long downtime during the boating season due to the difficulty of getting spare parts from the pump-out station supplier. Depending on the part that needs to be replaced, one solution can be to always keep a stock of this part in order to minimize the downtime. The buyer should specify a clause regarding this issue when buying a new station.

14) Long term responsibility

The eventuality of a supplier bankruptcy is rare, but it is anyway a risk to assess when purchasing a new pump-out station. It is important to define long term maintenance responsibilities in order ensure a continuous service of the station.
5.4 Suggestions for floating solutions

Floating stations are needed in the Swedish and Finnish archipelago: Users do not have to enter the harbour only to dump their sewage water and the station can be moved whenever it is needed.

However, some floating tanks made entirely in marine aluminium are having problems of corrosion in the inner part of the tank.

An alternative solution can be a floating station consisting of a pontoon that hosts a replaceable tank inside of it and a pump-out station on top. Even though users seem to prefer electrical pump, if there is no possibility of having electricity connection the pump has to be a hand pump.

For these kinds of solutions it is important to consider:

- The pontoon has to be big and sturdy enough to avoid stability problems and make the users feel comfortable when staying on it. Indicative pontoon dimensions are 3 x 12 m, in order to let big boats approach it easily

- The tank producer has to guarantee that the tank is made of a material resistant to corrosion for a time equal to the life span of the station, or easy to replace.
Keep the Archipelago Tidy, a Finnish partner in BATSECO-Boat project, has recently bought such type of floating station. In this case the pontoon has steps to facilitate the accessibility to the station both to small and big boats:

Fig. 5.4 – Floating pump-out station in Finland: The steps on one side allow easy access to boats with different heights. This pump-out station is equipped with a hand-pump and the tank is inside the pontoon.
5.5 Public procurement – an opportunity for improvement

As aforementioned, the pump-out stations market is lacking economic incentives and investments. Public procurement can be the instrument to help the market and improve the service as well. When procuring a pump-out station there are many aspects worthy of consideration already mentioned in this report, but some of them could be emphasised:

- One significant problem seems to be finding spare parts. This should be taken into consideration already in the procurement, by demanding that spare parts could be delivered within one week, for example.

- There are several examples of floating stations that have sharp edges, making it hard to dock. That problem should be easy enough to avoid if mentioned in the procurement.

- The drawback when using a hand-pump is that you need to be two persons to empty the boat tank: One that pumps and one that connects the nozzle. But on boats large enough to be equipped with toilets you tend to be more than one almost always. Hand-pumps seem to be much more reliable, with less down-time, and should be considerable cheaper, but it is important to keep in mind that users tend not to prefer this kind of pumps.

- The pump-out stations should be equipped with alarms both to indicate if the holding tank is full and to report if the station is out of service.

- Not in the procurement but in the service contract it should be defined the maximum downtime allowed during the boat season and the measures to guarantee it (e.g. periodical maintenance visits, with a defined frequency of the visits).

Finally, it is also important to highlight that the choice of the most suitable type of solution must consider the pump-out station as a whole with the wastewater system and all the related aspects such as capacity of the wastewater treatment plant, transport logistic, etc.
Attachment I

Market investigation in Sweden

Below a list of producers and catalogue of products. The list of producers might not be complete, and it can also vary over time. The prices, when reported, are only indicative.

**Latrina**

Latrina produces stationary and portable pump-out solutions.

The prices depend on the type of equipment/accessories provided.

**BAGA**

Baga is a Swedish enterprise specialized in wastewater solutions. They can produce pump-out stations and the solution can be customized to the needs of the customer.

More information about the different type of pumps can be found at [http://baga.se/avlopp/produkter/pumpar/](http://baga.se/avlopp/produkter/pumpar/)
EL-EFFEKT

This enterprise located in the Stockholm area is the Swedish retailer of products from Leestrom, one of the world leaders in this field. More information on [https://www.el-effekt.se/](https://www.el-effekt.se/) and [http://www.leestrom.eu/](http://www.leestrom.eu/)

Delivery time of 4 weeks, the transport fee is included in the pump-out station price.

For Finland and Estonia it is TOP MARINE the retailer of Leestrom products.

Stationary solutions

**LS60W**

- **Dimensions:** L = 400 mm, W = 395 mm, H = 1400 mm
- **Material:** Cabinet in stainless steel, pump in bronze
- **Pump:** Diaphragm pump
- **Electrical connection:** 230 V or 400 V
- **Draining Capacity:** 60 l/min
- **Hose:** different length available
- **Price:** 105600 kr (~10560 €) VAT included (84480 kr VAT excl.)

**LS160W-B**

- **Dimensions:** L = 1050 mm, W = 750 mm, H = 1300 mm
- **Material:** Cabinet in stainless steel, pump in bronze
- **Pump:** Diaphragm pump
- **Electrical connection:** 230 V or 400 V
- **Draining Capacity:** 60 l/min
- **Hose:** L = 15 m, diameter 38 mm
- **Price:** 130000 kr (~13000 €) VAT included
### Portable solution

**JETS**

Jets headquarters are set in Norway, with offices and retailers all around the world. They manufacture and sell vacuum sanitation systems.

In Sweden the retailer of pump out stations is [Bryggkompaniet](http://www.bryggkompaniet.se/), in Finland is [Septor OY](https://www.septor.fi/en/products/marine), while the reference for Estonia is Jets’ Lithuanian office.

The final solution can be customized to the needs of the customer, the pumps are standard. Here some examples of pumps, more information on Jets website.

Producers outside the project area

Below some of the main producers outside the project area:

**KECO**

Keco is one of the world leaders for marine pumps and marine pump-out stations products. The enterprise is set in the US, their retailer in Europe is the Dutch enterprise Sejsener, an European leader in the sector.

Complete catalogue of products at [https://www.pumpahead.com/](https://www.pumpahead.com/)
WASTECORP

Wastecorp is a leading OEM (original equipment manufacturer) of pumps and pump parts, with offices in the United States and Canada.

CEI - PORALU

This French enterprise is one of the world leaders for pump-out stations in harbours environment. They have distributors in many countries around the world, Sweden among others.

This kind of pump-out station is available in single, double or triple pump version.

<table>
<thead>

RMCS & ARABEL

RMCS works with different marine services such as pedestals, lightning solutions and also pump-out stations; it is based in the UK. Arabel is a Belgian enterprise that produces transformers and coils, but also equipment for marinas. They are both retailers of Leestrom pump-out stations.

Pontoon producers

The number of pontoons producers in the project area is quite high. Here reported a list of some of the biggest pontoons producers:

- Pontech, [http://pontech.se/](http://pontech.se/)
- AlfaBryggan, [https://www.alfabryggan.se/ehandel/14-pontoner](https://www.alfabryggan.se/ehandel/14-pontoner)
- Bryggkompaniet, [http://www.bryggkompaniet.se/](http://www.bryggkompaniet.se/)
- Marina Produkter, [http://www.marinaprodukter.se/](http://www.marinaprodukter.se/)
- SF Pontona Sverige, [https://www.sfpontona.se](https://www.sfpontona.se)

</tbody>
</table>
5. If you answered “Yes” to the previous question, please specify the type of problem you had.

$n_{\text{tot}} = 19$

<table>
<thead>
<tr>
<th>Answers</th>
</tr>
</thead>
<tbody>
<tr>
<td>The vacuum doesn’t work well</td>
</tr>
<tr>
<td>The cone of the nozzle did not fit the hole to the tank on the boat properly. The bad fit caused air leakage making it impossible to empty the tank. From now on I always carry a rubber gasket that solves the problem.</td>
</tr>
<tr>
<td>The septic tank of the station on the land was full.</td>
</tr>
<tr>
<td>Out of service. Difficult to reach the station due to its bad location</td>
</tr>
<tr>
<td>The hose nozzle was broken.</td>
</tr>
<tr>
<td>Usually broken, hard to reach the stations like the one in Airisto.</td>
</tr>
<tr>
<td>The hand-pump has not been working</td>
</tr>
<tr>
<td>The pump station in Kirjais, Nagu has been out of service for much of the summer. Now it seems to work.</td>
</tr>
<tr>
<td>The are very difficult to reach/localize</td>
</tr>
<tr>
<td>Out of service or broken</td>
</tr>
<tr>
<td>Out of service or broken</td>
</tr>
<tr>
<td>Out of service or not working well</td>
</tr>
<tr>
<td>The pump does not work</td>
</tr>
<tr>
<td>The pump got broken</td>
</tr>
<tr>
<td>The most common problem is that they are out of service</td>
</tr>
<tr>
<td>The pump-out station was out of service</td>
</tr>
<tr>
<td>Pump-out station out of service and the hose too short</td>
</tr>
<tr>
<td>The vacuum does not work</td>
</tr>
<tr>
<td>Stations out of service</td>
</tr>
</tbody>
</table>
6. What kind of station do you think is easier or more comfortable to use?

$\text{not} = 21$

<table>
<thead>
<tr>
<th>Answers:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manual pumps</td>
</tr>
<tr>
<td>The manual ones are a little bit more difficult to use if you are alone. Others work well (of those I tested).</td>
</tr>
<tr>
<td>Electric pumps.</td>
</tr>
<tr>
<td>The one that runs on electronic (electronic pump).</td>
</tr>
<tr>
<td>Large jetty with long enough suction cable. And it needs to be functioning properly, terribly annoying when you have docked and it doesn’t work.</td>
</tr>
<tr>
<td>All types works good for me.</td>
</tr>
<tr>
<td>Any type as long as they work.</td>
</tr>
<tr>
<td>Those with effective suction.</td>
</tr>
<tr>
<td>Floating, when it works.</td>
</tr>
<tr>
<td>All types works good but the floating ones are easier to use.</td>
</tr>
<tr>
<td>Any station that works well.</td>
</tr>
<tr>
<td>Any type is ok.</td>
</tr>
<tr>
<td>Pump in a harbour where we can take fresh water.</td>
</tr>
<tr>
<td>Sturdy</td>
</tr>
<tr>
<td>Floating station</td>
</tr>
<tr>
<td>Those connected to the wastewater system.</td>
</tr>
<tr>
<td>Don’t understand the question.</td>
</tr>
<tr>
<td>Electric, but I don’t use it for my own boat.</td>
</tr>
<tr>
<td>Land stations.</td>
</tr>
<tr>
<td>Automatic suction is of course easier, but I would rather choose a floating station rather than taking the one in the shore port if I don’t need to go to the harbour for other reasons.</td>
</tr>
</tbody>
</table>
7. Do you think it would be useful to have a toilet together with the pump-out station?

$\text{n}_{\text{tot}} = 30$

<table>
<thead>
<tr>
<th></th>
<th>n</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes, there is need for that</td>
<td>19</td>
<td>63,33%</td>
</tr>
<tr>
<td>No, no need for that</td>
<td>8</td>
<td>26,67%</td>
</tr>
<tr>
<td>Open answer</td>
<td>3</td>
<td>10%</td>
</tr>
</tbody>
</table>

Text

- Open answer: no opinion
- Open answer: on islands with a lot of visitors it is needed, but otherwise not
- Open answer: Appreciate the landbased dry-toilets. They are enough for many boaters. Suction emptying and chemical toilets are mostly unnecessary.
8. Any comments about what you think is important to consider for the installation of the new pump-out stations?

\[ n_{\text{tot}} = 11 \]

**Answers:**

- Build those that do not smell bad.
- Service and maintenance! Too often, pump stations are out of order. Very frustrating to find a pump that does not work if you have gone through a long way to empty your tank.
- That there is fresh water and that it is possible to clean the equipment
- Would be good with electric drainage, ie a sufficiently strong suction so that even really big boats can empty their tank.
- More functional stations with sufficiently long suction hoses. And a phone number where you can call and report if the station is broken. And much easier to use, larger piers so it is possible to moor.
- The pier must be large and have space for big boats
- I use these stations in other boats. They don’t work properly, no suction power, or they do not work at all.
- Why not having two pumps, one on each side of the floating stations, so if one pump breaks you can use the other, or two boats can simultaneously empty their tank.
- That they really are there, as it is advertised.
- That they are in places that make it is easy to moor.
Questions asked in the interviews to ports managers and maintenance technicians:
